

FSFFL NEXT

Fresh Provider Capture & Y1 Pipeline Diagnostic

Management Report - 19 Sep 2026

Outcome B - Provider evidence itself is extreme / semantically unsuitable

Bottom line: the current FSFFL arithmetic is not creating the extreme Year-1 totals. Fresh Razzball evidence is already extreme before normalization or averaging. FFToday is materially lower and looks like ordinary full-season projection data. FSFFL preserves the provider stats, takes the exact equal-weight mean, and scores that mean correctly under the league rules.

The key governance concern is upstream evidence suitability, especially Razzball horizon semantics. The captured page identifies itself as 2026 projections but also says: "Updated from NFL Preseason through rest of season." That page should not continue as an expected full-season Forecast input until management governs the source/horizon meaning.

What was executed

- Recovered the already-completed Stage 0 state; code-path discovery was not repeated.
- Confirmed the protected repository state before execution: main unchanged; PR #147 still open and held.
- Persisted a pre-execution capture manifest before provider network access.
- Ran one governed fresh capture. FFToday and Razzball succeeded. CBS and NFL Fantasy failed their full-season/content gates and were not substituted into the two-source ensemble.
- Persisted parser-table substitutes, provider parsed rows, provider-specific normalized rows, the equal-weight ensemble, the league-scored Y1 board, mapping/parser audits, named-player traces, and population diagnostics.
- Performed zero Forecast fits, zero tuning, zero route changes, zero production changes, zero merges, zero deploys, and zero promotion actions.

Why the result is clear

All three pipeline parity checks were exact across the fresh 335-player board:

- Raw provider row -> normalized canonical stats: maximum absolute discrepancy 0.0.
- Normalized providers -> equal-weight ensemble: maximum absolute discrepancy 0.0.
- Ensemble raw stats -> league-scored Year 1: maximum absolute discrepancy 0.0.

Concrete example: Bijan Robinson

- Fresh FFToday: 324.9 half-PPR; 1,402 rush yd; 707 rec yd; 84 receptions.
- Fresh Razzball: 646.3 half-PPR recomputed from raw stats; 2,904 rush yd; 1,313 rec yd; 142 receptions.
- FSFFL equal-weight ensemble: 485.6 half-PPR.

This is the causal pattern the audit was designed to distinguish: Razzball is already extreme, and FSFFL produces the mathematical midpoint of ordinary FFToday evidence and extreme Razzball evidence.

Population-level provider evidence

Fresh Razzball raw rows crossed clearly extreme season-total thresholds before FSFFL normalization:

- 31 players with more than 5,000 passing yards.
- 20 players with more than 2,000 rushing yards.
- 12 players with more than 2,000 receiving yards.

These are provider-side totals. Provider-native fantasy-point columns are not reused as raw stats, per-game data are not multiplied into season totals, and the league-scoring recomposition check is exact.

Named fresh Y1 outputs

- Bijan Robinson: 485.60 half-PPR.
- Jahmyr Gibbs: 460.25 half-PPR.
- Christian McCaffrey: 433.45 half-PPR.
- Puka Nacua: 401.45 half-PPR.
- Sam Darnold: 383.06 half-PPR.
- Aaron Rodgers: 344.29 half-PPR.

Provider and horizon interpretation

FFToday: materially lower fresh evidence consistent with ordinary season-projection magnitudes for the named players.

Razzball: raw table rows themselves contain unusually large passing, rushing, and receiving totals. The page metadata also says "Updated from NFL Preseason through rest of season." This is a material provider-evidence / horizon-semantic issue for this use case.

FSFFL pipeline: no material acquisition, parsing, normalization, mapping, ensemble, or scoring defect was found in the controlled fresh run. The pipeline faithfully preserves and averages the evidence it receives.

Important limitation

This fresh capture diagnoses the current executable pipeline only. It is not a reconstruction of the missing 18 Sep 2026 provider rows. The result explains why the current board is extreme, but it does not prove that the same provider evidence was returned on 18 Sep. The September 18 historical coordinate remains unrecovered.

Governed next question

Do not change weights, repair player projections, or refit Forecast in this workstream. The smallest next management decision is a governed Razzball evidence-suitability / horizon-validation rule before this page can continue serving as expected full-season Forecast input.

Execution provenance

Research branch: research/future-state-resolution-phase34-resume
Pre-execution manifest head: ff14f367440b394238564835b4fe65f84ae656f7

PR #147 held head: 3e63cd61602d0832acf0a30dcc5bee0b13ceeb63
Capture start: 2026-09-19T09:20:35.049901+00:00
Capture complete: 2026-09-19T09:20:38.183096+00:00
Capture runtime: 3.133 seconds
Successful fresh provider captures: 1
Forecast fits / tuning / route / production changes: 0 / 0 / 0 / 0

Durable result

Classification: B - PROVIDER EVIDENCE ITSELF IS EXTREME / SEMANTICALLY UNSUITABLE.

Fresh FFToday is ordinary. Fresh Razzball rows are extreme before FSFFL normalization.
Equal-weight arithmetic and league scoring reproduce exactly. No material FSFFL arithmetic inflation was found.

Fresh data is not a reconstruction of 2026-09-18.

Hard stop

Diagnostic complete. Stop for management review. Do not repair the Y1 materializer, change providers, refit Forecast, rerun the P0 credibility gate, or reopen Intrinsic/Shapley in this task.
